The covalent bond: One reason atoms form bonds is that they are able to share electrons with other atoms to complete the valence shells of both. The valence shells of the lightest two elements, hydrogen and helium, can hold up to two electrons; the valence shells of most of the familiar elements can accommodate eight electrons.

### Why Do Most Atoms Form Chemical Bonds? | Sciencing

The two types of bonding are covalent, for the sharing of electrons between atoms, and ionic, for the net transfer of electrons between atoms. Covalent or ionic bonding will determine the type of compound that will be formed. In Chapter 1, we used atomic theory to describe the structure of the

Electronegativity An atom's electronegativity value refers to the amount of "pull" that an atom's nucleus exerts on another atom's electrons when it is involved in a bond. Atoms of different elements typically have different electronegativities. As you move across the periodic table from left to right, electronegativity increases.
